

1) (10 pts) DSN (Dynamic Memory Management in C)

The struct `Monster_List` maintains a list of monsters using a dynamically sized array of pointers to `Monster`. A function prototype is given for a function `initializeMonster`, which takes in a pointer to a `Monster` **that must already be pointing to memory that is allocated**, and then fills that memory with information about a default monster. Write a function `getDefaultMonsters` which takes in a positive integer `n`, creates a pointer to a `Monster_List`, allocates room for it, and then fills it with `n` default Monsters, and then returns a pointer to the `Monster_list` created. (Note: You must call `initializeMonster` in your solution.)

```
typedef struct Monster {
    // Details not necessary to solve the problem.
} Monster;

typedef struct Monster_List {
    Monster** mArray;
    int numMonsters;
} Monster_List;

// Initializes the monster pointed to by mPtr to be the default
// monster.
void initializeMonster(Monster* mPtr);

Monster_List* getDefaultMonsters(int n) {

}
```
